

Preferential Attachment and Network Evolution

[Ahmet Onur Durahim](#)

How the Class Fits Together

Properties

Small diameter,
Edge clustering

Scale-free

Strength of weak ties,
Core-periphery

Densification power law,
Shrinking diameters

Complex Graph Structure

Information virality,
Memetracking

Models

Small-world model,
Erdős-Rényi model

Preferential attachment,
Copying model

Kronecker Graphs

Microscopic model of
evolving networks

Graph Neural Networks

Independent cascade model,
Game theoretic model

Algorithms

Decentralized search

PageRank, Hubs and
authorities

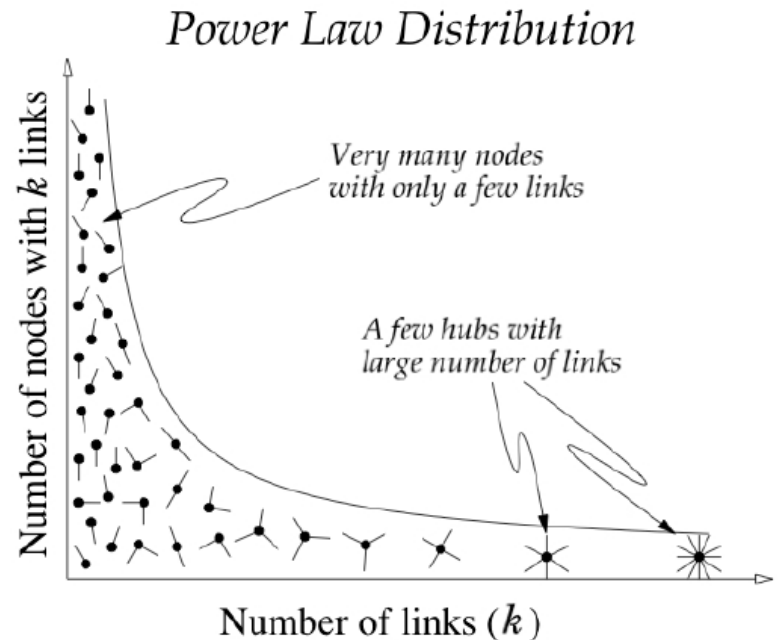

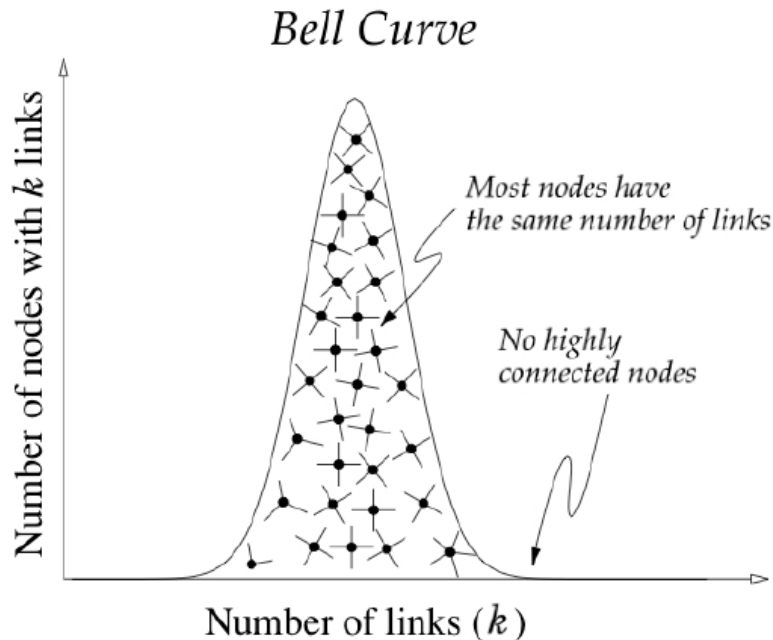

Community detection:
Girvan-Newman, Modularity

Link prediction,
Supervised random walks

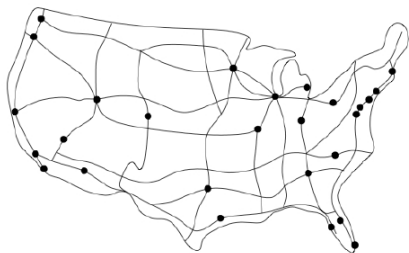

Node Classification
Graph Representation Learning

Influence maximization,
Outbreak detection, LIM

Exponential vs. Power-Law

Model: **G_{np}**

?

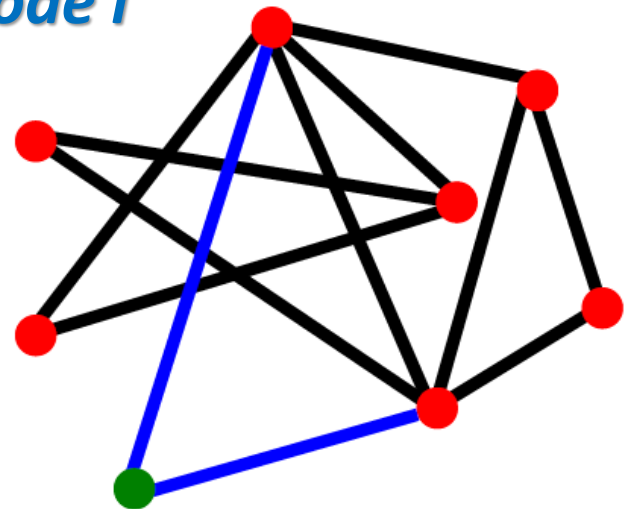

Model: Preferential Attachment

- **Preferential attachment**

[Price '65, Albert-Barabasi ['99](#), Mitzenmacher ['03](#)]

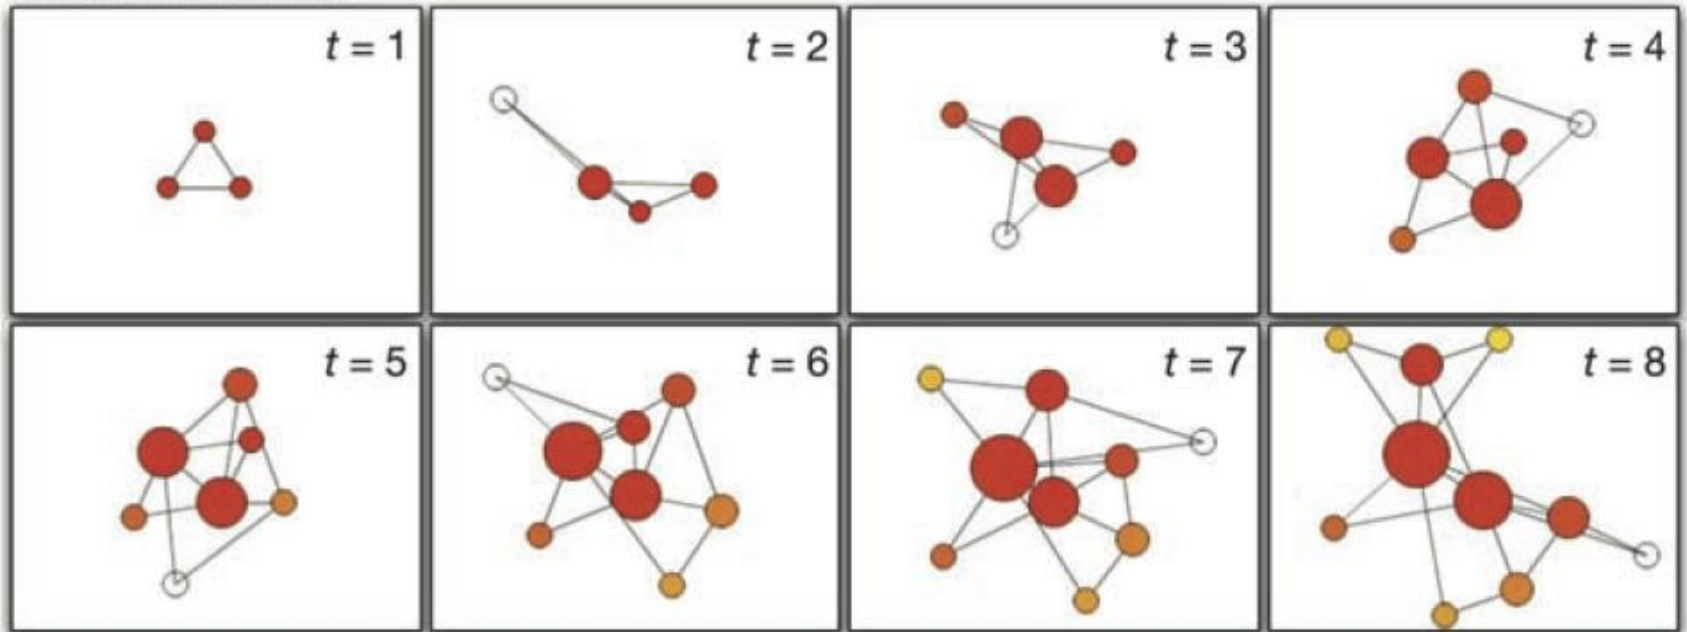

- Nodes arrive in order **1,2,...,n**
- At step **j**, let **d_i** be the degree of node **$i < j$**
- **A new node j** arrives and creates **m out-links**
- Prob. of j linking to a previous node i is ***proportional to degree d_i of node i***

$$P(j \rightarrow i) = \frac{d_i}{\sum_k d_k}$$

Preferential Attachment Model

Scale-Free Model

Barabasi, 1999

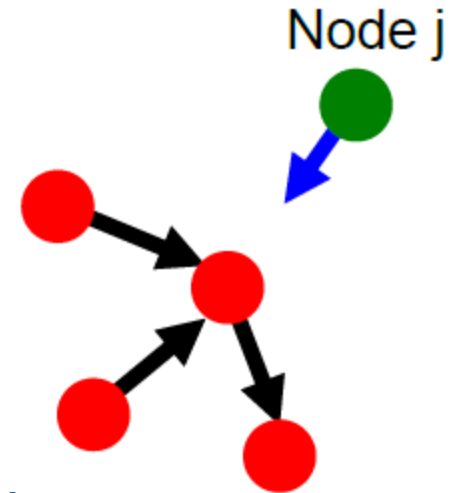

Rich Get Richer

- New nodes are more likely to link to nodes that already have high degree
- Herbert Simon's result:
 - Power-laws arise from “*Rich get richer*” (cumulative advantage)
- Examples [Price '65]
 - Citations: New citations to a paper are proportional to the number it already has
 - Herding: If a lot of people cite a paper, then it must be good, and therefore I should cite it too
 - Sociology: *Matthew effect*
 - Eminent scientists often get more credit than a comparatively unknown researcher, even if their work is similar
 - http://en.wikipedia.org/wiki/Matthew_effect

The Exact Model

We will analyze the following model:

- Nodes arrive in order $1, 2, 3, \dots, n$
- When **node j is created** it makes a **single out-link** to an earlier node i chosen:
 - 1) with prob. p , node j links to i chosen **uniformly at random** (from among all earlier nodes)
 - 2) with prob. $1 - p$, node j chooses i uniformly at random and links to node l that i points to
 - **This is same as saying:** with prob. $1 - p$, node j links to node l with prob. proportional to d_l (the in-degree of l)
 - **Our graph is directed:** Every node has out-degree **1**

Degree Distribution

- What is $F(k)$, the fraction of nodes that has degree less than k at time t ?
 - How many nodes have degree $< k$?

$$d_i(t) = \frac{p}{q} \left(\left(\frac{t}{i} \right)^q - 1 \right) < k$$

- Solve for i and obtain: $i > t \left(\frac{q}{p} k + 1 \right)^{-\frac{1}{q}}$

- There are t nodes total at time t so the fraction $F(k)$ is:

$$F(k) = 1 - \left[\frac{q}{p} k + 1 \right]^{-\frac{1}{q}}$$

Degree Distribution

- What is the fraction of nodes with degree exactly k ?

– Take derivative of $F(k)$:

- $F(k)$ is CDF, so $F'(k)$ is the PDF!

$$F(k) = 1 - \left[\frac{q}{p} k + 1 \right]^{-\frac{1}{q}}$$

$$F'(k) = \frac{1}{p} \left[\frac{q}{p} k + 1 \right]^{-1 - \frac{1}{q}} \Rightarrow \alpha = 1 + \frac{1}{1 - p}$$

q.e.d.

Pref. Attachment: Good news

- Preferential attachment gives power-law degrees!
- Intuitively reasonable process
- Can tune p to get the observed exponent
 - On the web, $P[\text{node has degree } d] \sim d^{-2.1}$
 - $2.1 = 1 + 1/(1-p) \rightarrow p \sim 0.1$

Pref. Attachment: Bad news

- Preferential attachment is not so good at predicting network structure
 - Age-degree correlation
 - *Solution:* Node fitness (virtual degree)
 - Links among high degree nodes:
 - On the web nodes sometime avoid linking to each other
- Further questions:
 - What is a reasonable model for how people sample through network node and link to them?
 - *Short random walks*
 - *Effect of search engines – reaching pages based on the number of links to them*

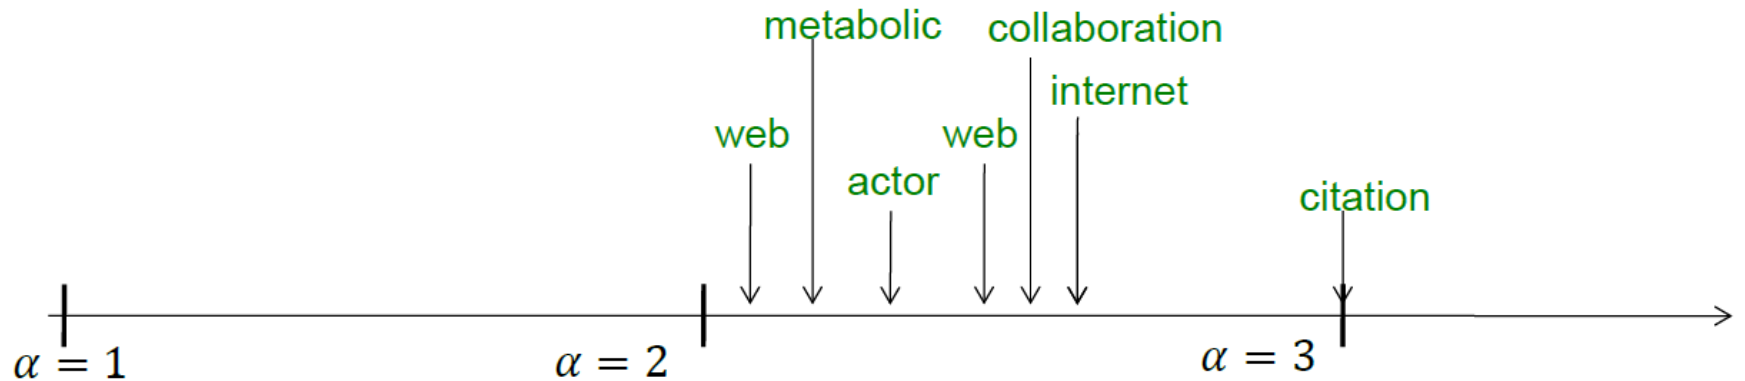

Many Models lead to Power-Laws

- **Copying mechanism (directed network)** (Kleinberg)
 - Select a node and an edge of this node
 - Attach to the endpoint of this edge
- **Walking on a network (directed network)**
 - The new node connects to a node, then to every first, second, ... neighbor of this node
- **Attaching to edges**
 - Select an edge and attach to both endpoints of this edge
- **Node duplication**
 - Duplicate a node with all its edges
 - Randomly prune edges of new node

Distances in Preferential Attachment

Ultra small world	$\bar{h} = \left\{ \begin{array}{l} \text{const} \\ \frac{\log \log n}{\log(\alpha-1)} \\ \frac{\log n}{\log \log n} \\ \log n \end{array} \right.$	$\alpha = 2$	Size of the biggest hub is of order $O(N)$. Most nodes can be connected within two steps, thus the average path length will be independent of the network size.
		$2 < \alpha < 3$	The average path length increases slower than logarithmically. In G_{np} all nodes have comparable degree, thus most paths will have comparable length. In a scale-free network vast majority of the path go through the few high degree hubs, reducing the distances between nodes.
$\alpha = 3$		Some models produce $\alpha = 3$. This was first derived by Bollobas et al. for the network diameter in the context of a dynamical model, but it holds for the average path length as well.	
Small world		$\alpha > 3$	The second moment of the distribution is finite, thus in many ways the network behaves as a random network. Hence the average path length follows the result that we derived for the random network model earlier.
		Avg. path length	Degree exponent

Summary: Scale-Free Networks

Second moment $\langle k^2 \rangle$ diverges

$\langle k^2 \rangle$ finite

Average $\langle k \rangle$ diverges

Average $\langle k \rangle$ finite

Ultra small world behavior

Small world

Regime full of anomalies...

The scale-free behavior is relevant

Behaves like a random network

Model Comparison

	Random	BA model	WS model	Empirical networks
$P(k)$	$\frac{\lambda^k e^{-\lambda}}{k!}$	k^{-3}	poisson like	power law
C	$\langle k \rangle / N$	$N^{-0.75}$	const	large
$\langle L \rangle$	$\frac{\log(N)}{\log(\langle k \rangle)}$	$\frac{\log(N)}{\log \log(N)}$	$\log(N)$	small
